1. Introduction. A univariate time series is a sample of data values in dependence on time, where for each element of a set of time points, $t(i)$, there exists one corresponding data point, $x(i)$. The insight is that one should be able to rearrange the values of a function freely, while preserving the value of the integral. This process of rearrangement can convert a very pathological function into one that is "nice" from the point of view of integration, and thus let such pathological functions be integrated. - Folland Real Analysis Solution Chapter 2
